

1. Introduction. This is an implementation of the Irregular Terrain Model (ITM), version 1.2.2. The properties of this model and the algorithm defining it have been given in the references:

Hufford, G. A., A. G. Longley, and W. A. Kissick (1982), A guide to the use of the ITS Irregular Terrain Model in the area prediction mode, NTIA Report 82-100. (NTIS Order No. PB82-217977)

Hufford, G. A. (1995), The ITS Irregular Terrain Model, version 1.2.2, the Algorithm.

In particular, the implementation here follows the latter description (“the Algorithm”) as closely as seems possible. Indeed, there are below direct references to the equation numbers in “the Algorithm.” These are indicated with terminology such as “[Alg 3.5]” which thus refers to equation (3.5) in that document.

2.

We begin with a declaration of the two important common blocks. The first lists the primary output values and the primary input parameters. The second contains important secondary or derived parameters.

For the primary parameters, the input values (which are often introduced by subroutines such as *qlrps*) are

The controlling mode *mdp*, distance *dist*, antenna structural heights *hg*, wave number (radio frequency) *wn*, terrain irregularity parameter *dh*, surface refractivity *ens*, earth’s effective curvature *gme*, surface transfer impedance of the ground *zgnd*, antenna effective heights *he*, horizon distances *dl*, and horizon elevation angles *the*.

while the output values are

The error indicator *kwx*, and the reference attenuation *aref*.

⟨Primary parameters 2⟩ ≡

common /prop/ *kwx*, *aref*, *mdp*, *dist*, *hg*(2), *wn*, *dh*, *ens*, *gme*, *zgnd*, *he*(2), *dl*(2), *the*(2)
complex *zgnd*

This code is used in sections 4, 10, 17, 22, 28, 41, 42, 43, and 47.

3. The secondary parameters are computed in *lrprop* and consist of

The line-of-sight distance *dlsa*, scatter distance *dx*, line-of-sight coefficients *ael*, *ak1*, *ak2*, diffraction coefficients *aed*, *emd*, scatter coefficients *aes*, *ems*, smooth earth horizon distances *dls*, total horizon distance *dla*, and total bending angle *tha*.

⟨Secondary parameters 3⟩ ≡

common /propa/ *dlsa*, *dx*, *ael*, *ak1*, *ak2*, *aed*, *emd*, *aes*, *ems*, *dls*(2), *dla*, *tha*

This code is used in sections 4, 10, 17, and 22.

4. **LRprop.** The Longley-Rice propagation program. This is the basic program; it returns the reference attenuation *aref*.

```

subroutine lrprop•(d)

@(  

  Version 1.2.2 (Aug 71/Mar 77/Aug 84) of the Irregular Terrain  

  Model  

  by Longley and Rice (1968)  

@)  

  <Primary parameters 2>  

  <Secondary parameters 3>  

save wlos, wscat, dmin, xae  

logical wlos, wscat, wq  

parameter (third = 1./3.)  

  <LRprop 5>  

  aref = max(aref, 0.)  

return  

end

```

5. The value of *mdp* controls some of the program flow. When it equals -1 we are in the point-to-point mode, when 1 we are beginning the area mode, and when 0 we are continuing the area mode. The assumption is that when one uses the area mode, one will want a sequence of results for varying distances.

```

<LRprop 5> ≡
  if (mdp ≠ 0) then
    <Do secondary parameters 6>  

    <Check parameter ranges 7>  

    <Diffraction coefficients 9>  

  endif  

  if (mdp ≥ 0) then  

    mdp = 0  

    dist = d  

  endif  

  if (dist > 0.) then  

    <Check distance 8>  

  endif  

  if (dist < dlsa) then  

    <Line-of-sight calculations 15>  

  endif  

  if (dist ≤ 0. | dist ≥ dlsa) then  

    <Troposcatter calculations 20>  

  endif

```

This code is used in section 4.

6.

⟨Do secondary parameters 6⟩ ≡

```

do j = 1,2
  dls(j) = sqrt(2.*he(j)/gme) // [Alg 3.5]
enddo
dlsa = dls(1) + dls(2) // [Alg 3.6]
dla = dl(1) + dl(2) // [Alg 3.7]
tha = max(the(1) + the(2), -dla*gme) // [Alg 3.8]
wlos = F
wscat = F

```

This code is used in section 5.

7.

⟨Check parameter ranges 7⟩ ≡

```

if (wn < 0.838 | wn > 210.) kwx = max(kwx,1)
do j = 1,2
  if (hg(j) < 1. | hg(j) > 1000.) kwx = max(kwx,1)
enddo
do j = 1,2
  if (abs(the(j)) > 200 * 10-3 | dl(j) < 0.1*dls(j) | dl(j) > 3.*dls(j)) kwx = max(kwx,3)
enddo
if ( ens < 250. | ens > 400. | gme < 75 * 10-9 | gme > 250 * 10-9 | Real(zgnd) ≤ abs(Imag(zgnd)) |
  wn < 0.419 | wn > 420. ) kwx = 4
do j = 1,2
  if (hg(j) < 0.5 | hg(j) > 3000.) kwx = 4
enddo
dmin = abs(he(1) - he(2))/200 * 10-3

```

This code is used in section 5.

8.

⟨Check distance 8⟩ ≡

```

if (dist > 1000 * 103) kwx = max(kwx,1)
if (dist < dmin) kwx = max(kwx,3)
if (dist < 1 * 103 | dist > 2000 * 103) kwx = 4

```

This code is used in section 5.

9. The Diffraction Region. This is the region beyond the smooth-earth horizon at d_{Lsa} and short of where tropospheric scatter takes over. It is a key central region and the associated coefficients must always be computed.

⟨Diffraction coefficients 9⟩ ≡

```

q = adiff10(0.)
xae = (wn*gme2)-third // [Alg 4.2]
d3 = max(dlsa, 1.3787*xae + dla) // [Alg 4.3]
d4 = d3 + 2.7574*xae // [Alg 4.4]
a3 = adiff10(d3) // [Alg 4.5]
a4 = adiff10(d4) // [Alg 4.6]
emd = (a4 - a3)/(d4 - d3) // [Alg 4.7]
aed = a3 - emd*d3 // [Alg 4.8]

```

This code is used in section 5.

10. The function *adiff* finds the “diffraction attenuation” at the distance d . It uses a convex combination of smooth earth diffraction and double knife-edge diffraction. A call with $d = 0$. sets up initial constants.

```

function adiff•(d)
  ⟨Primary parameters 2⟩
  ⟨Secondary parameters 3⟩
  save wd1, xd1, afo, qk, ah, xht
  parameter (third = 1./3.)

  if (d ≡ 0.) then
    ⟨Prepare initial diffraction constants 11⟩
  else
    ⟨Compute diffraction attenuation 12⟩
  endif
  return
end

```

11.

⟨Prepare initial diffraction constants 11⟩ ≡

```

q = hg(1)*hg(2)
qk = he(1)*he(2) - q
if (mdp < 0) q = q + 10.
wd1 = sqrt(1. + qk/q)
xd1 = dla + tha/gme // xd1 and wd1 are parts of Q in [Alg 4.9]
q = (1. - 0.8*exp(-dlsa/50 * 10^3))*dh
q = 0.78*q*exp(-(q/16.)^0.25) // sigma_h(dlsa)
afo = min(15., 2.171*log(1. + 4.77 * 10^-4 * hg(1)*hg(2)*wn*q)) // [Alg 4.10]
qk = 1./cabs(zgnd)
aht = 20. // [Alg 6.7]
xht = 0.
do j = 1, 2
  a = 0.5*dl(j)^2/he(j) // [Alg 4.15]
  wa = (a*wn)^third // [Alg 4.16]
  pk = qk/wa // [Alg 4.17]
  q = (1.607 - pk)*151.0*wa*dl(j)/a // [Alg 4.18] and [Alg 6.2]
  xht = xht + q // [Alg 4.19], the height-gain part
  aht = aht + fht_14(q, pk) // [Alg 4.20]
enddo
adiff_10 = 0.

```

This code is used in section 10.

12.

⟨Compute diffraction attenuation 12⟩ ≡

```

th = tha + d*gme // [Alg 4.12]
ds = d - dla
q = 0.0795775*wn*ds*th^2
adiff_10 = aknfe_13(q*dl(1)/(ds + dl(1))) + aknfe_13(q*dl(2)/(ds + dl(2))) // [Alg 4.14]
a = ds/th
wa = (a*wn)^third // [Alg 4.16]
pk = qk/wa // [Alg 4.17]
q = (1.607 - pk)*151.0*wa*th + xht // [Alg 4.18] and [Alg 6.2]
ar = 0.05751*q - 4.343*log(q) - aht // [Alg 4.20]
q = (wd1 + xd1/d)*min(((1. - 0.8*exp(-d/50 * 10^3))*dh*wn), 6283.2)
wd = 25.1/(25.1 + sqrt(q)) // [Alg 4.9]
adiff_10 = ar*wd + (1. - wd)*adiff_10 + afo // [Alg 4.11]

```

This code is used in section 10.

13. The attenuation due to a single knife edge—the Fresnel integral (in decibels) as a function of v^2 . The approximation is that given in [Alg 6.1].

```

function aknfe•(v2)
  if (v2 < 5.76) then
    aknfe• = 6.02 + 9.11*sqrt(v2) - 1.27*v2
  else
    aknfe• = 12.953 + 4.343*log(v2)
  endif
  return
end

```

14. The height-gain over a smooth spherical earth—to be used in the “three radii” method. The approximation is that given in [Alg 6.4].

```

function fht•(x,pk)
  if (x < 200.) then
    w = -log(pk)
    if (pk < 1 · 10-5 | x*w3 > 5495.) then
      fht• = -117.
      if (x > 1.) fht• = 17.372*log(x) + fht• // [Alg 6.5]
    else
      fht• = 2.5 · 10-5*x2/pk - 8.686*w - 15. // [Alg 6.6]
    endif
  else
    fht• = 0.05751*x - 4.343*log(x) // [Alg 6.3]
    if (x < 2000) then
      w = 0.0134*x*exp(-0.005*x)
      fht• = (1. - w)*fht• + w*(17.372*log(x) - 117.) // [Alg 6.4]
    endif
  endif
  return
end

```

15. The Line-of-sight Region.

⟨Line-of-sight calculations 15⟩ ≡

```

if ( $\neg wlos$ ) then
  ⟨Line-of-sight coefficients 16⟩
   $wlos = \mathcal{T}$ 
endif
if ( $dist > 0.$ )  $aref = ael + ak1 * dist + ak2 * \log(dist)$  // [Alg 4.1]

```

This code is used in section 5.

16.

⟨Line-of-sight coefficients 16⟩ ≡

```

 $q = alos_{17}(0.)$

```

27. The Statistics.

LRprop will stand alone to compute *aref*. To complete the story, however, one must find the quantiles of the attenuation and this is what *avar* will do. It, too, is a stand alone subroutine, except that it requires the output from *LRprop*, as well as values in a “variability parameters” common block. These latter values consist of

A control switch *lvar*, the standard deviation of situation variability (confidence) *sgc*, the desired mode of variability *mdvar*, and the climate indicator *klim*.

Of these, *sgc* is output and may be used to answer the inverse problem: with what confidence will a threshold signal level be exceeded.

⟨Variability parameters 27⟩ ≡

common /*propv* / *lvar*, *sgc*, *mdvar*, *klim*

This code is used in sections 28, 42, and 43.

28. When in the area prediction mode, one needs a threefold quantile of attenuation which corresponds to the fraction q_T of time, the fraction q_L of locations, and the fraction q_S of “situations.” In the point-to-point mode, one needs only q_T and q_S . For efficiency, *avar* is written as a function of the “standard normal deviates” z_T , z_L , and z_S corresponding to the requested fractions. Thus, for example, $q_T = Q(z_T)$ where $Q(z)$ is the “complementary standard normal distribution.” For the point-to-point mode one sets $z_L = 0$ which corresponds to the median $q_L = 0.50$.

The subprogram is written trying to reduce duplicate calculations. This is done through the switch *lvar*. On first entering, set *lvar* = 5. Then all parameters will be initialized, and *lvar* will be changed to 0. If the program is to be used to find several quantiles with different values of z_T , z_L , or z_S , then *lvar* should be 0, as it is. If the distance is changed, set *lvar* = 1 and parameters that depend on the distance will be recomputed. If antenna heights are changed, set *lvar* = 2; if the frequency, *lvar* = 3; if the mode of variability *mdvar*, set *lvar* = 4; and finally if the climate is changed, set *lvar* = 5. The higher the value of *lvar*, the more parameters will be recomputed.

40. Preparatory Subroutines.

The next three subroutines may be used to introduce input parameters for *LRprop*. One first calls *qlrps*₄₁ and then either *qlra*₄₂ (for the area prediction mode) or *qlrpf*₄₃ (for the point-to-point mode).

41. This subroutine converts the frequency *f_{mhz}*, the surface refractivity reduced to sea level *en₀* and general system elevation *z_{sys}*, and the polarization and ground constants *eps*, *sgm*, to wave number *wn*, surface refractivity *ens*, effective earth curvature *gme*, and surface impedance *zgnd*. It may be used with either the area prediction or the point-to-point mode.

```

subroutine qlrps(fmhz,zsys,en0,ipol,eps,sgm)
  ⟨Primary parameters 2⟩
  complex zq
  data gma/157·10-9/
  wn = fmhz/47.7 // [Alg 1.1]
  ens = en0
  if (zsys ≠ 0.) ens = ens*exp(-zsys/9460.) // [Alg 1.2]
  gme = gma*(1. - 0.04665*exp(ens/179.3)) // [Alg 1.3]
  zq = cmplx(eps, 376.62*sgm/wn) // [Alg 1.5]
  zgnd = csqrt(zq - 1.)
  if (ipol ≠ 0) zgnd = zgnd/zq // [Alg 1.4]
  return
end

```

42. This is used to prepare the model in the area prediction mode. Normally, one first calls *qlrps* and then *qlra*. Before calling the latter, one should have defined in the ⟨Primary parameters 2⟩ the antenna heights *hg*, the terrain irregularity parameter *dh*, and (probably through *qlrps*) the variables *wn*, *ens*, *gme*, and *zgn*. The input *kst* will define siting criteria for the terminals, *klimx* the climate, and *mdvarx* the mode of variability. If $klimx \leq 0$ or $mdvarx < 0$ the associated parameters remain unchanged.

The operational flow of a calling program might appear as follows.

```

    set kwx = 0, lvar = 5;
    define hg, dh and call qlrps;
    optionally, define mdvar, klim;
    call qlra;
    loop for selected distances d:
        set lvar = max(lvar, 1);
        call lrprop(d);
        loop for selected quantiles:
            A = avar(...);
            output A;
        repeat;
    repeat;
    check kwx;
    end

subroutine qlra (kst, klimx, mdvarx)
    dimension kst(2)

    ⟨Primary parameters 2⟩
    ⟨Variability parameters 27⟩

    do j = 1, 2
        if (kst(j) ≤ 0) then
            he(j) = hg(j)
        else
            q = 4.
            if (kst(j) ≠ 1) q = 9.
            if (hg(j) < 5.) q = q*sin(0.3141593*hg(j))
            he(j) = hg(j) + (1. + q)*exp(-min(20., 2.*hg(j)/max(1·10-3, dh)))
        endif
        q = sqrt(2.*he(j)/gme)
        dl(j) = q*exp(-0.07*sqrt(dh/max(he(j), 5.)))
        the(j) = (0.65*dh*(q/dl(j) - 1.) - 2.*he(j))/q
    enddo

    mdp = 1
    lvar = max(lvar, 3)
    if (mdvarx ≥ 0) then
        mdvar = mdvarx
        lvar = max(lvar, 4)
    endif
    if (klimx > 0) then
        klim = klimx
        lvar = 5
    endif
    return
end

```

43. This subroutine may be used to prepare for the point-to-point mode. Since the path is fixed, it has only one value of *aref* and therefore at the end of the routine there is a call to *lrprop*. To complete the process one needs to call *avar* for whatever quantiles are desired.

This mode requires the terrain profile lying between the terminals. This should be a sequence of surface elevations at points along the great circle path joining the two points. It should start at the ground beneath the first terminal and end at the ground beneath the second. In the present routine it is assumed that the elevations are *equispaced* along the path. They are stored in the array *pfl* along with two defining parameters. We will have $pfl(1) = enp$, the number (as a real value) of increments in the path; $pfl(2) = xi$, the length of each increment; $pfl(3) = z(0)$, the beginning elevation; and then $pfl(np + 3) = z(np)$, the last elevation.

The operational flow of a calling program might appear as follows.

```

set kwx = 0, lvar = 5;
define pfl, hg and call qlrps;
optionally, define mdvar, klim;
call qlrpfl;
loop for selected quantiles:
    A = avar(...);
    output A;
repeat;
check kwx;
end

subroutine qlrpfl•(pfl,klimx,mdvarx)
  dimension pfl(*)

  ⟨Primary parameters 2⟩
  ⟨Variability parameters 27⟩

  dimension xl(2)

  dist = pfl(1)*pfl(2)

  go to 2
1: t = rp/(t + rp)
  qerf. = exp(-0.5*x2)*rrt2pi*(((b5*t + b4)*t + b3)*t + b2)*t + b1)*t
2: if (x < 0.) qerf. = 1. - qerf.
  return
end

```

51. The inverse of *qerf*—the solution for x to $q = Q(x)$. The approximation is due to C. Hastings, Jr. (“Approximations for digital computers,” Princeton Univ. Press, 1955) and the maximum error should be 4.5×10^{-4} .

```

function qerfi.(q)

data c0, c1, c2 /2.515516698, 0.802853, 0.010328/
data d1, d2, d3 /1.432788, 0.189269, 0.001308/

  x = 0.5 - q
  t = amax1(0.5 - abs(x), 0.000001)
  t = sqrt(-2.*alog(t))
  qerfi. = t - ((c2*t + c1)*t + c0)/(((d3*t + d2)*t + d1)*t + 1.)
  if (x < 0.) qerfi. = -qerfi.
  return
end

```

52. This routine provides a quantile. It reorders the array a so that $a(j), j = 1 \dots i_r$ are all greater than or equal to all $a(i), i = i_r \dots nn$. In particular, $a(i_r)$ will have the same value it would have if a were completely sorted in descending order. The returned value is $qtile = a(i_r)$.

```

@m Qt0. #:0
@m Qt1. #:0
@m Qt2. #:0
@m Qt3. #:0

function qtile.(nn,a,ir)
    dimension a(nn)

    m = 1
    n = nn
    k = min(max(1, ir), n)
Qt0.: continue
    q = a(k)
    i0 = m
    j1 = n
Qt1.: continue
    do i = i0, n
        if (a(i) < q) go to Qt2.
    enddo
    i = n
Qt2.: do j = j1, m, -1
        if (a(j) > q) go to Qt3.
    enddo
    j = m
Qt3.: if (i < j) then
    r = a(i)
    a(i) = a(j)
    a(j) = r
    i0 = i + 1
    j1 = j - 1
    go to Qt1.
    else if (i < k) then
    a(k) = a(i)
    a(i) = q
    m = i + 1

    n = j - 1
    go to Qt0.
    endif
    qtile. = q
    return
end

```

53. A linear least squares fit between x_1 , x_2 to the function described by the array z . This array must have a special format: $z(1) = en$, the number of equally large intervals, $z(2) = \xi$, the interval length, and $z(j+3)$, $j = 0, \dots, n$, function values. The output consists of values of the required line, z_0 at 0, z_n at $x_t = n\xi$.

```

subroutine zlsq1.(z,x1,x2,z0,zn)
  dimension z(*)

  xn = z(1)
  xa = aint(dim(x1/z(2),0.))
  xb = xn - aint(dim(xn,x2/z(2)))
  if (xb ≤ xa) then
    xa = dim(xa,1.)
    xb = xn - dim(xn,xb+1.)
  endif
  ja = xa
  jb = xb
  n = jb - ja
  xa = xb - xa
  x = -0.5*xa
  xb = xb + x
  a = 0.5*(z(ja+3) + z(jb+3))
